Package 'restriktor'

October 4, 2023

Title Restricted Statistical Estimation and Inference for Linear
Models

Version 0.5-30

Description Allow for easy-to-use testing or evaluating of linear equality and inequality restrictions about parameters and effects in (generalized) linear statistical models.

Depends R(>= 4.0.0)

Imports boot, ic.infer, lavaan(>= 0.6-10), MASS, mvtnorm, quadprog,
norm, ggplot2

License GPL (>= 2)

LazyData yes

URL https://restriktor.org

NeedsCompilation no

restriktor-package   *Package for equality and inequality restricted estimation, model selection and hypothesis testing*

Description

Package `restriktor` implements estimation, testing and evaluating of linear equality and inequality restriktions about parameters and effects for univariate and multivariate normal models and generalized linear models.

Details

Package:	restriktor
Type:	Package
Version:	0.5-30
Date:	2023-10-03
License:	GPL (>=2)
LazyLoad:	yes

Function `restriktor` estimates the parameters of an univariate and multivariate linear model (`lm`), robust estimation of the linear model (`rlm`) or a generalized linear model (`glm`) subject to linear equality and/or inequality restriktions. The real work horses are the `conLM`, `conMLM`, the `conRLM`, and the `conGLM` functions. A major advantage of **restriktor** is that the constraints can be specified by a text-based description. This means that users do not have to specify the complex constraint matrix (comparable with a contrast matrix) themselves.

The function `restriktor` offers the possibility to compute (model robust) standard errors under the restriktions. The parameter estimates can also be bootstrapped, where bootstrapped standard errors and confidence intervals are available via the summary function. Moreover, the function computes the Generalized Order-restricted Information Criterion (GORIC), which is a modification of the AIC and a generalization of the ORIC.

The function `iht` (alias `conTest`) conducts restricted hypothesis tests. F, Wald/LRT and score test-statistics are available. The null-distribution of these test-statistics takes the form of a mixture of F-distributions. The mixing weights (a.k.a. chi-bar-square weights or level probabilities) can be computed using the multivariate normal distribution function with additional Monte Carlo steps or via a simulation approach. Bootstrap methods are available to calculate the mixing weights and to compute the p-value directly. Parameters estimates under the null- and alternative-hypothesis are available from the summary function.

The function `goric` (generalized order-restricted information criterion) computes GORIC values, weights and relative-weights or GORICA (generalized order-restricted information crittion approximation) values, weights and relative weights. The GORIC(A) values are comparable to the AIC values. The function offers the possibility to evaluate an order-restricted hypothesis against its complement, the unconstrained hypothesis or against a set of hypotheses. For now, only one order-restricted hypothesis can be evaluated against its complement but work is in progress to evaluate a set of order-restricted hypothesis against its complement.

The package makes use of various other R packages: **quadprog** is used for restricted estimation, **boot** for bootstrapping, **ic.infer** for computing the mixing weights based on the multivariate normal distribution, **lavaan** for parsing the constraint syntax.

Value

The output of function `restriktor` belongs to S3 class `conLM`, `conMLM`, `conRLM` or `conGLM`.

The output of function `conTest` belongs to S3 class `conTest`.

These classes offer print and summary methods.

Acknowledgements

This package uses as an internal function the function `nchoosek` from **ic.infer**, which is originally from **vsn**, authored by Wolfgang Huber, available under LGPL.

The output style of the `iht` print function is strongly inspired on the summary of the `ic.test` function from the **ic.infer** package.

## Data preparation
## Ages (in months) at which an infant starts to walk alone.
DATA <- ZelazoKolb1972
DATA <- subset(DATA, Group != "Control")

## unrestricted linear model
fit.lm <- lm(Age ~ -1 + Group, data = DATA)
summary(fit.lm)

## restricted linear model with restriktions that the walking
## exercises would not have a negative effect of increasing the
## mean age at which a child starts to walk.

myConstraints <- ' GroupActive  < GroupPassive;
                   GroupPassive < GroupNo '

fit.con <- restriktor(fit.lm, constraints = myConstraints)
summary(fit.con)
```

AngerManagement	*Reduction of aggression levels Dataset (4 treatment groups)*

Description

The anger management dataset consists of reduction of aggression levels between week 1 (intake) and week 8 (end of training) from four different treatment groups (No-exercises, Physical-exercises, Behavioral-exercises, combination of physical and behavioral exercises).

Usage

```
data(AngerManagement)
```

Format

A data frame of 40 observations of 4 treatment variables and covariate age.

Anger reduction in aggression levels

Group No, Physical, Behavioral, Both

Age persons' age

bootstrapD	*Bootstrapping a Lavaan Model*

Description

Bootstrap the D statistic.

Usage

```
bootstrapD(h0 = NULL, h1 = NULL, constraints, type = "A",
           bootstrap.type = "bollen.stine", R = 1000L,
           return.D = FALSE, double.bootstrap = "no",
           double.bootstrap.R = 500L, double.bootstrap.alpha = 0.05,
           verbose = FALSE, warn = -1L,
           parallel = c("no", "multicore", "snow"), ncpus = 1L, cl = NULL,
           seed = NULL)

  ## S3 method for class 'conTestLavaan'
print(x, digits = max(3, getOption("digits") - 2), ...)
```

Arguments

h0	An object of class [lavaan](). The restricted model.
h1	An object of class [lavaan](). The unrestricted model.
x	an object of class conTestLavaan.
constraints	The imposed (in)equality constraints on the model.
type	hypothesis test type "A", "B".
bootstrap.type	If "parametric", the parametric bootstrap is used. If "bollen.stine", the semi-nonparametric Bollen-Stine bootstrap is used. The default is set to "bollen.stine".
R	Integer. The number of bootstrap draws.
return.D	Logical; if TRUE, the function returns bootstrapped D-values.
double.bootstrap	
	If "standard" (default) the genuine double bootstrap is used to compute an additional set of plug-in p-values for each bootstrap sample. If "no", no double bootstrap is used. If "FDB", the fast double bootstrap is used to compute second level LRT-values for each bootstrap sample. Note that the "FDB" is experimental and should not be used by inexperienced users.
double.bootstrap.R	
	Integer; number of double bootstrap draws. The default value is set to 249.
double.bootstrap.alpha	
	The significance level to compute the adjusted alpha based on the plugin p-values. Only used if double.bootstrap = "standard". The default value is set to 0.05.
verbose	If TRUE, show information for each bootstrap draw.
warn	Sets the handling of warning messages. See [options]().
parallel	The type of parallel operation to be used (if any). If missing, the default is "no".
ncpus	Integer: number of processes to be used in parallel operation: typically one would chose this to the number of available CPUs.
cl	An optional **parallel** or **snow** cluster for use if parallel = "snow". If not supplied, a cluster on the local machine is created for the duration of the bootstrapLavaan or bootstrapLRT call.
digits	the number of significant digits to use when printing.

| ... | no additional arguments for now. |
| seed | An integer to set the seed. Or NULL if no reproducible seeds are needed. |

Value

A bootstrap p value, calculated as the proportion of bootstrap samples with a D statistic at least as large as the D statistic for the original data.

```

Burns	*Relation between the response variable PTSS and gender, age, TBSA,*
	guilt and anger.

Description

Simulated dataset based on the original model parameters. The original data are based on two cohort studies in children from 0 to 4 and 8 to 18 years old with burns and their mother.

Usage

```
data(Burns)
```

Format

A data frame of 278 observations of 4 variables.

PTSS post-traumatic stress symptoms

gender gender

age age in years

TBSA estimated percentage total body surface area affected by second and third degree burns

guilt parental guilt feelings in relation to the burn event

anger parental anger feelings in relation to the burn event

conTestC	*one-sided t-test for iht*

Description

conTestC tests linear inequality restricted hypotheses for (robust) linear models by a one-sided t-test. This method is based on the union-intersection principle. It is called by the conTest function if all restrictions are equalities. For more information see details.

Usage

```
## S3 method for class 'restriktor'
conTestC(object, ...)
```

Arguments

object	an object of class restriktor.
...	no additional arguments for now.

Details

Hypothesis test Type C:

- Test H0: at least one restriction false ("<") against HA: all constraints strikty true (">"). This test is based on the intersection-union principle. Note that, this test only makes sense in case of no equality constraints.

The null-distribution of hypothesis test Type C is based on a t-distribution (one-sided). Its power can be poor in case of many inequalty constraints. Its main role is to prevent wrong conclusions from significant results from hypothesis test Type A.

Value

An object of class conTest, for which a print is available. More specifically, it is a list with the following items:

CON	a list with useful information about the constraints.
Amat	constraints matrix.
bvec	vector of right-hand side elements.
meq	number of equality constraints.
test	same as input.
Ts	test-statistic value.
df.residual	the residual degrees of freedom.
pvalue	tail probability for Ts.
b.unrestr	unrestricted regression coefficients.
b.restr	restricted regression coefficients.
Sigma	variance-covariance matrix of unrestricted model.
R2.org	unrestricted R-squared.
R2.reduced	restricted R-squared.
boot	"no", not used (yet).
model.org	original model.

```

---

conTestF	*F-bar test for iht*

Description

conTestF tests linear equality and/or inequality restricted hypotheses for linear models by F-tests. It can be used directly and is called by the conTest function if test = "F".

Usage

```
## S3 method for class 'conLM'
conTestF(object, type = "A", neq.alt = 0,
         boot = "no", R = 9999, p.distr = rnorm,
         parallel = "no", ncpus = 1L, cl = NULL, seed = 1234,
         verbose = FALSE, control = NULL, ...)

## S3 method for class 'conRLM'
conTestF(object, type = "A", neq.alt = 0,
         boot = "no", R = 9999, p.distr = rnorm,
         parallel = "no", ncpus = 1L, cl = NULL, seed = 1234,
         verbose = FALSE, control = NULL, ...)

## S3 method for class 'conGLM'
conTestF(object, type = "A", neq.alt = 0,
         boot = "no", R = 9999, p.distr = rnorm,
         parallel = "no", ncpus = 1L, cl = NULL, seed = 1234,
         verbose = FALSE, control = NULL, ...)
```

Arguments

object	an object of class conLM, conRLM or conGLM.
type	hypothesis test type "A", "B", "C", "global", or "summary" (default). See details for more information.
neq.alt	integer: number of equality constraints that are maintained under the alternative hypothesis (for hypothesis test type "B"), see example 3.
boot	the null-distribution of these test-statistics (except under type "C") takes the form of a mixture of F-distributions. The tail probabilities can be computed directly via bootstrapping; if "parametric", the p-value is computed based on the parametric bootstrap. By default, samples are drawn from a normal distribution with mean zero and varance one. See p.distr for other distributional options. If "model.based", a model-based bootstrap method is used. Instead of computing the p-value via simulation, the p-value can also be computed using the chi-bar-square weights. If "no", the p-value is computed based on the weights obtained via simulation (mix.weights = "boot") or using the multivariate normal distribution function (mix.weights = "pmvnorm"). Note that, these weights are already available in the restriktor objected and do not need to be estimated again. However, there are two exception for objects of class conRLM, namely for computing the p-value for the robust test = "Wald" and the robust "score". In these cases the weights need to be recalculated.
R	integer; number of bootstrap draws for boot. The default value is set to 9999.
p.distr	random generation distribution for the parametric bootstrap. For all available distributions see ?distributions. For example, if rnorm, samples are drawn from the normal distribution (default) with mean zero and variance one. If rt,

samples are drawn from a t-distribution. If rchisq, samples are drawn from a chi-square distribution. The distributional parameters will be passed in via ....

parallel   the type of parallel operation to be used (if any). If missing, the default is set "no".

ncpus   integer: number of processes to be used in parallel operation: typically one would chose this to the number of available CPUs.

cl   an optional parallel or snow cluster for use if parallel = "snow". If not supplied, a cluster on the local machine is created for the duration of the conTest call.

seed   seed value. The default value is set to 1234.

verbose   logical; if TRUE, information is shown at each bootstrap draw.

control   a list of control arguments:

- absval tolerance criterion for convergence (default = sqrt(.Machine$double.eps)). Only used for model of class lm.
- maxit the maximum number of iterations for the optimizer (default = 10000). Only used for model of class mlm (not yet supported).
- tol numerical tolerance value. Estimates smaller than tol are set to 0.

...   additional arguments to be passed to the p.distr function.

Details

The following hypothesis tests are available:

- Type A: Test H0: all constraints with equalities ("=") active against HA: at least one inequality restriction (">") strictly true.

- Type B: Test H0: all constraints with inequalities (">") (including some equalities ("=")) active against HA: at least one restriction false (some equality constraints may be maintained).

- Type C: Test H0: at least one restriction false ("<") against HA: all constraints strikty true (">"). This test is based on the intersection-union principle (Silvapulle and Sen, 2005, chp 5.3). Note that, this test only makes sense in case of no equality constraints.

- Type global: equal to Type A but H0 contains additional equality constraints. This test is analogue to the global F-test in lm, where all coefficients but the intercept equal 0.

The null-distribution of hypothesis test Type C is based on a t-distribution (one-sided). Its power can be poor in case of many inequalty constraints. Its main role is to prevent wrong conclusions from significant results from hypothesis test Type A.

The exact finite sample distributions of the non-robust F-, score- and LR-test statistics based on restricted OLS estimates and normally distributed errors, are a mixture of F-distributions under the null hypothesis (Wolak, 1987). In agreement with Silvapulle (1992), we found that the results based on these mixtures of F-distributions approximate the tail probabilities of the robust tests better than their asymptotic distributions. Therefore, all p-values for hypothesis test Type "A", "B" and "global" are computed based on mixtures of F-distributions.

Note that, in case of equality constraints only, the null-distribution of the (robust) F-test statistics is based on an F-distribution. The (robust) Wald- and (robust) score-test statistics are based on chi-square distributions.

Value

An object of class conTest, for which a print is available. More specifically, it is a list with the following items:

CON	a list with useful information about the constraints.
Amat	constraints matrix.
bvec	vector of right-hand side elements.
meq	number of equality constraints.
meq.alt	same as input neq.alt.
iact	number of active constraints.
type	same as input.
test	same as input.
Ts	test-statistic value.
df.residual	the residual degrees of freedom.
pvalue	tail probability for Ts.
b.eqrestr	equality restricted regression coefficients. Only available for type = "A" and type = "global", else b.eqrestr = NULL.
b.unrestr	unrestricted regression coefficients.
b.restr	restricted regression coefficients.
b.restr.alt	restricted regression coefficients under HA if some equality constraints are maintained. Only available for type = "B" else b.restr.alt = NULL.
Sigma	variance-covariance matrix of unrestricted model.
R2.org	unrestricted R-squared, not available for objects of class conGLM.
R2.reduced	restricted R-squared, not available for objects of class conGLM.
boot	same as input.
model.org	original model.

conTestLRT   *Likelihood-ratio-bar test for iht*

Description

conTestLRT tests linear equality and/or inequality restricted hypotheses for linear models by LR-tests. It can be used directly and is called by the conTest function if test = "LRT".

Usage

```
## S3 method for class 'conLM'
conTestLRT(object, type = "A", neq.alt = 0,
           boot = "no", R = 9999, p.distr = rnorm,
           parallel = "no", ncpus = 1L, cl = NULL, seed = 1234,
           verbose = FALSE, control = NULL, ...)

## S3 method for class 'conGLM'
conTestLRT(object, type = "A", neq.alt = 0,
           boot = "no", R = 9999, p.distr = rnorm,
           parallel = "no", ncpus = 1L, cl = NULL, seed = 1234,
           verbose = FALSE, control = NULL, ...)

## S3 method for class 'conMLM'
conTestLRT(object, type = "A", neq.alt = 0,
           boot = "no", R = 9999, p.distr = rnorm,
```

```
parallel = "no", ncpus = 1L, cl = NULL, seed = 1234,
verbose = FALSE, control = NULL, ...)
```

Arguments

object	an object of class conLM, conMLM or conGLM.
type	hypothesis test type "A", "B", "C", "global", or "summary" (default). See details for more information.
neq.alt	integer: number of equality constraints that are maintained under the alternative hypothesis (for hypothesis test type "B"), see example 3.
boot	the null-distribution of these test-statistics (except under type "C", see details) takes the form of a mixture of F-distributions. The tail probabilities can be computed directly via bootstrapping; if "parametric", the p-value is computed based on the parametric bootstrap. By default, samples are drawn from a normal distribution with mean zero and varance one. See p.distr for other distributional options. If "model.based", a model-based bootstrap method is used. Instead of computing the p-value via simulation, the p-value can also be computed using the chi-bar-square weights. If "no", the p-value is computed based on the weights obtained via simulation (mix.weights = "boot") or using the multivariate normal distribution function (mix.weights = "pmvnorm"). Note that, these weights are already available in the restriktor objected and do not need to be estimated again. However, there are two exception for objects of class conRLM, namely for computing the p-value for the robust test = "Wald" and the robust "score". In these cases the weights need to be recalculated.
R	integer; number of bootstrap draws for boot. The default value is set to 9999.
p.distr	random generation distribution for the parametric bootstrap. For all available distributions see ?distributions. For example, if rnorm, samples are drawn from the normal distribution (default) with mean zero and variance one. If rt, samples are drawn from a t-distribution. If rchisq, samples are drawn from a chi-square distribution. The random generation distributional parameters will be passed in via . . . .
parallel	the type of parallel operation to be used (if any). If missing, the default is set "no".
ncpus	integer: number of processes to be used in parallel operation: typically one would chose this to the number of available CPUs.
cl	an optional parallel or snow cluster for use if parallel = "snow". If not supplied, a cluster on the local machine is created for the duration of the conTest call.
seed	seed value. The default value is set to 1234.
verbose	logical; if TRUE, information is shown at each bootstrap draw.
control	a list of control arguments:
	• absval tolerance criterion for convergence (default = sqrt(.Machine$double.eps)). Only used for model of class lm.
	• maxit the maximum number of iterations for the optimizer (default = 10000). Only used for model of class mlm (not yet supported).
	• tol numerical tolerance value. Estimates smaller than tol are set to 0.
...	additional arguments to be passed to the p.distr function.

Details

The following hypothesis tests are available:

- Type A: Test H0: all constraints with equalities ("=") active against HA: at least one inequality restriction (">") strictly true.

- Type B: Test H0: all constraints with inequalities (">") (including some equalities ("=")) active against HA: at least one restriction false (some equality constraints may be maintained).

- Type C: Test H0: at least one restriction false ("<") against HA: all constraints strikty true (">"). This test is based on the intersection-union principle (Silvapulle and Sen, 2005, chp 5.3). Note that, this test only makes sense in case of no equality constraints.

- Type global: equal to Type A but H0 contains additional equality constraints. This test is analogue to the global F-test in lm, where all coefficients but the intercept equal 0.

The null-distribution of hypothesis test Type C is based on a t-distribution (one-sided). Its power can be poor in case of many inequalty constraints. Its main role is to prevent wrong conclusions from significant results from hypothesis test Type A.

The exact finite sample distributions of the non-robust F-, score- and LR-test statistics based on restricted OLS estimates and normally distributed errors, are a mixture of F-distributions under the null hypothesis (Wolak, 1987). In agreement with Silvapulle (1992), we found that the results based on these mixtures of F-distributions approximate the tail probabilities of the robust tests better than their asymptotic distributions. Therefore, all p-values for hypothesis test Type ″A″, ″B″ and ″global″ are computed based on mixtures of F-distributions.

Value

An object of class conTest, for which a print is available. More specifically, it is a list with the following items:

`CON`	a list with useful information about the constraints.
`Amat`	constraints matrix.
`bvec`	vector of right-hand side elements.
`meq`	number of equality constraints.
`meq_alt`	same as input neq.alt.
`iact`	number of active constraints.
`type`	same as input.
`test`	same as input.
`Ts`	test-statistic value.
`df.residual`	the residual degrees of freedom.
`pvalue`	tail probability for `Ts`.
`b_eqrestr`	equality restricted regression coefficients. Only available for type = ″A″ and type = ″global″, else b.eqrestr = NULL.
`b_unrestr`	unrestricted regression coefficients.
`b_restr`	restricted regression coefficients.

b_restr_alt	restricted regression coefficients under HA if some equality constraints are maintained. Only available for type = "B" else b_restr_alt = NULL.
Sigma	variance-covariance matrix of unrestricted model.
R2_org	unrestricted R-squared, not available for objects of class conGLM.
R2_reduced	restricted R-squared, not available for objects of class conGLM.
boot	same as input.
model_org	original model.

             boot = "no", R = 9999, p.distr = rnorm,
             parallel = "no", ncpus = 1L, cl = NULL, seed = 1234,
             verbose = FALSE, control = NULL, ...)

## S3 method for class 'conGLM'
conTestScore(object, type = "A", neq.alt = 0,
             boot = "no", R = 9999, p.distr = rnorm,
             parallel = "no", ncpus = 1L, cl = NULL, seed = 1234,
             verbose = FALSE, control = NULL, ...)
```

Arguments

object	an object of class conLM, conRLM or conGLM.
type	hypothesis test type "A", "B", "C", "global", or "summary" (default). See details for more information.
neq.alt	integer: number of equality constraints that are maintained under the alternative hypothesis (for hypothesis test type "B"), see example 3.
boot	the null-distribution of these test-statistics (except under type "C", see details) takes the form of a mixture of F-distributions. The tail probabilities can be computed directly via bootstrapping; if "parametric", the p-value is computed based on the parametric bootstrap. By default, samples are drawn from a normal distribution with mean zero and varance one. See p.distr for other distributional options. If "model.based", a model-based bootstrap method is used. Instead of computing the p-value via simulation, the p-value can also be computed using the chi-bar-square weights. If "no", the p-value is computed based on the weights obtained via simulation (mix.weights = "boot") or using the multivariate normal distribution function (mix.weights = "pmvnorm"). Note that, these weights are already available in the restriktor objected and do not need to be estimated again. However, there are two exception for objects of class conRLM, namely for computing the p-value for the robust test = "Wald" and the robust "score". In these cases the weights need to be recalculated.
R	integer; number of bootstrap draws for boot. The default value is set to 9999.
p.distr	random generation distribution for the parametric bootstrap. For all available distributions see ?distributions. For example, if rnorm, samples are drawn from the normal distribution (default) with mean zero and variance one. If rt, samples are drawn from a t-distribution. If rchisq, samples are drawn from a

	chi-square distribution. The random generation distributional parameters will be passed in via . . . .
parallel	the type of parallel operation to be used (if any). If missing, the default is set "no".
ncpus	integer: number of processes to be used in parallel operation: typically one would chose this to the number of available CPUs.
cl	an optional parallel or snow cluster for use if parallel = "snow". If not supplied, a cluster on the local machine is created for the duration of the conTest call.
seed	seed value. The default value is set to 1234.
verbose	logical; if TRUE, information is shown at each bootstrap draw.
control	a list of control arguments:

- absval tolerance criterion for convergence (default = sqrt(.Machine$double.eps)). Only used for model of class lm.
- maxit the maximum number of iterations for the optimizer (default = 10000). Only used for model of class mlm (not yet supported).
- tol numerical tolerance value. Estimates smaller than tol are set to 0.

...	additional arguments to be passed to the p.distr function.

Details

The following hypothesis tests are available:

- Type A: Test H0: all constraints with equalities ("=") active against HA: at least one inequality restriction (">") strictly true.

- Type B: Test H0: all constraints with inequalities (">") (including some equalities ("=")) active against HA: at least one restriction false (some equality constraints may be maintained).

- Type C: Test H0: at least one restriction false ("<") against HA: all constraints strikty true (">"). This test is based on the intersection-union principle (Silvapulle and Sen, 2005, chp 5.3). Note that, this test only makes sense in case of no equality constraints.

- Type global: equal to Type A but H0 contains additional equality constraints. This test is analogue to the global F-test in lm, where all coefficients but the intercept equal 0.

The null-distribution of hypothesis test Type C is based on a t-distribution (one-sided). Its power can be poor in case of many inequalty constraints. Its main role is to prevent wrong conclusions from significant results from hypothesis test Type A.

The exact finite sample distributions of the non-robust F-, score- and LR-test statistics based on restricted OLS estimates and normally distributed errors, are a mixture of F-distributions under the null hypothesis (Wolak, 1987). In agreement with Silvapulle (1992), we found that the results based on these mixtures of F-distributions approximate the tail probabilities of the robust tests better than their asymptotic distributions. Therefore, all p-values for hypothesis test Type "A", "B" and "global" are computed based on mixtures of F-distributions.

Value

An object of class conTest, for which a print is available. More specifically, it is a list with the following items:

CON	a list with useful information about the constraints.
Amat	constraints matrix.
bvec	vector of right-hand side elements.
meq	number of equality constraints.

conTestWald   *Wald-bar test for robust iht*

Description

conTestWald tests linear equality and/or inequality restricted hypotheses for linear models by
Wald-tests. It can be used directly and is called by the conTest function if test = "Wald".

Usage

```
## S3 method for class 'conRLM'
conTestWald(object, type = "A", neq.alt = 0,
            boot = "no", R = 9999, p.distr = rnorm,
            parallel = "no", ncpus = 1L, cl = NULL, seed = 1234,
            verbose = FALSE, control = NULL, ...)
```

Arguments

object	an object of class conRLM.
type	hypothesis test type "A", "B", "C", "global", or "summary" (default). See details for more information.
neq.alt	integer: number of equality constraints that are maintained under the alternative hypothesis (for hypothesis test type "B"), see example 3.
boot	the null-distribution of these test-statistics (except under type "C", see details) takes the form of a mixture of F-distributions. The tail probabilities can be computed directly via bootstrapping; if "parametric", the p-value is computed based on the parametric bootstrap. By default, samples are drawn from a normal

distribution with mean zero and varance one. See `p.distr` for other distribu-
tional options. If `"model.based"`, a model-based bootstrap method is used. In-
stead of computing the p-value via simulation, the p-value can also be computed
using the chi-bar-square weights. If `"no"`, the p-value is computed based on
the weights obtained via simulation (`mix.weights = "boot"`) or using the mul-
tivariate normal distribution function (`mix.weights = "pmvnorm"`). Note that,
these weights are already available in the restriktor objected and do not need
to be estimated again. However, there are two exception for objects of class
conRLM, namely for computing the p-value for the robust `test = "Wald"` and the
robust `"score"`. In these cases the weights need to be recalculated.

R   integer; number of bootstrap draws for `boot`. The default value is set to 9999.

p.distr   random generation distribution for the parametric bootstrap. For all available
                    distributions see `?distributions`. For example, if `rnorm`, samples are drawn
                    from the normal distribution (default) with mean zero and variance one. If `rt`,
                    samples are drawn from a t-distribution. If `rchisq`, samples are drawn from a
                    chi-square distribution. The random generation distributional parameters will
                    be passed in via `...`.

parallel   the type of parallel operation to be used (if any). If missing, the default is set
                    "no".

ncpus   integer: number of processes to be used in parallel operation: typically one
                    would chose this to the number of available CPUs.

cl   an optional parallel or snow cluster for use if parallel = "snow". If not supplied,
                    a cluster on the local machine is created for the duration of the conTest call.

seed   seed value. The default value is set to 1234.

verbose   logical; if TRUE, information is shown at each bootstrap draw.

control   a list of control arguments:

                    • absval tolerance criterion for convergence (default = sqrt(.Machine$double.eps)).
                      Only used for model of class lm.
                    • maxit the maximum number of iterations for the optimizer (default = 10000).
                      Only used for model of class mlm (not yet supported).
                    • tol numerical tolerance value. Estimates smaller than tol are set to 0.

...   additional arguments to be passed to the p.distr function.

Details

The following hypothesis tests are available:

- Type A: Test H0: all constraints with equalities ("=") active against HA: at least one inequality
  restriction (">") strictly true.

- Type B: Test H0: all constraints with inequalities (">") (including some equalities ("=")) active
  against HA: at least one restriction false (some equality constraints may be maintained).

- Type C: Test H0: at least one restriction false ("<") against HA: all constraints strikty true
  (">"). This test is based on the intersection-union principle (Silvapulle and Sen, 2005, chp
  5.3). Note that, this test only makes sense in case of no equality constraints.

- Type global: equal to Type A but H0 contains additional equality constraints. This test is analogue to the global F-test in lm, where all coefficients but the intercept equal 0.

The null-distribution of hypothesis test Type C is based on a t-distribution (one-sided). Its power can be poor in case of many inequalty constraints. Its main role is to prevent wrong conclusions from significant results from hypothesis test Type A.

The exact finite sample distributions of the non-robust F-, score- and LR-test statistics based on restricted OLS estimates and normally distributed errors, are a mixture of F-distributions under the null hypothesis (Wolak, 1987). In agreement with Silvapulle (1992), we found that the results based on these mixtures of F-distributions approximate the tail probabilities of the robust tests better than their asymptotic distributions. Therefore, all p-values for hypothesis test Type "A", "B" and "global" are computed based on mixtures of F-distributions.

Value

An object of class conTest, for which a print is available. More specifically, it is a list with the following items:

CON	a list with useful information about the constraints.
Amat	constraints matrix.
bvec	vector of right-hand side elements.
meq	number of equality constraints.
meq.alt	same as input neq.alt.
iact	number of active constraints.
type	same as input.
test	same as input.
Ts	test-statistic value.
df.residual	the residual degrees of freedom.
pvalue	tail probability for Ts.
b.eqrestr	equality restricted regression coefficients. Only available for type = "A" and type = "global", else b.eqrestr = NULL.
b.unrestr	unrestricted regression coefficients.
b.restr	restricted regression coefficients.
b.restr.alt	restricted regression coefficients under HA if some equality constraints are maintained. Only available for type = "B" else b.restr.alt = NULL.
Sigma	variance-covariance matrix of unrestricted model.
R2.org	unrestricted R-squared, not available for objects of class conGLM.
R2.reduced	restricted R-squared, not available for objects of class conGLM.
boot	same as input.
model.org	original model.

conTest_ceq   *Tests for iht with equality constraints only*

Description

conTest_ceq tests linear equality restricted hypotheses for (robust) linear models by F-, Wald-, and score-tests. It can be used directly and is called by the conTest function if all restrictions are equalities.

Usage

```
## S3 method for class 'conLM'
conTest_ceq(object, test = "F", boot = "no",
            R = 9999, p.distr = rnorm, parallel = "no",
            ncpus = 1L, cl = NULL, seed = 1234, verbose = FALSE, ...)
```

```
## S3 method for class 'conRLM'
conTest_ceq(object, test = "F", boot = "no",
            R = 9999, p.distr = rnorm, parallel = "no",
            ncpus = 1L, cl = NULL, seed = 1234, verbose = FALSE, ...)

## S3 method for class 'conGLM'
conTest_ceq(object, test = "F", boot = "no",
            R = 9999, p.distr = rnorm, parallel = "no",
            ncpus = 1L, cl = NULL, seed = 1234, verbose = FALSE, ...)
```

Arguments

object	an object of class conLM, conRLM or conGLM.
test	test statistic; for information about the null-distribution see details.
	• for object of class lm and glm; if "F" (default), the classical F-statistic is computed. If "Wald", the classical Wald-statistic is computed. If "score", the classical score test statistic is computed.
	• for object of class rlm; if "F" (default), a robust likelihood ratio type test statistic (Silvapulle, 1992a) is computed. If "Wald", a robust Wald test statistic (Silvapulle, 1992b) is computed. If "score", a score test statistic (Silvapulle, 1996) is computed.
boot	if "parametric", the p-value is computed based on the parametric bootstrap. See p.distr for available distributions. If "model.based", a model-based bootstrap method is used. Model-based bootstrapping is not supported for the conGLM object yet.
R	integer; number of bootstrap draws for boot. The default value is set to 9999.
p.distr	the p.distr function is specified by this function. For all available distributions see ?distributions. For example, if rnorm, samples are drawn from the normal distribution (default) with mean zero and variance one. If rt, samples are drawn from a t-distribution. If rchisq, samples are drawn from a chi-square distribution. The distributional parameters will be passed in via . . . .
parallel	the type of parallel operation to be used (if any). If missing, the default is set "no".
ncpus	integer: number of processes to be used in parallel operation: typically one would chose this to the number of available CPUs.
cl	an optional parallel or snow cluster for use if parallel = "snow". If not supplied, a cluster on the local machine is created for the duration of the conTest call.
seed	seed value. The default value is set to 1234.
verbose	logical; if TRUE, information is shown at each bootstrap draw.
...	additional arguments to be passed to the p.distr function.

Value

An object of class conTest, for which a print is available. More specifically, it is a list with the following items:

CON	a list with useful information about the constraints.
Amat	constraints matrix.
bvec	vector of right-hand side elements.
meq	number of equality constraints.
test	same as input.
Ts	test-statistic value.
df.residual	the residual degrees of freedom.
pvalue	tail probability for Ts.
b_unrestr	unrestricted regression coefficients.
b_restr	restricted regression coefficients.
R2_org	unrestricted R-squared.
R2_reduced	restricted R-squared.

conTest_summary   *function for computing all available hypothesis tests*

Description

conTest_summary computes all available hypothesis tests and returns and object of class conTest
for which a print function is available. The conTest_summary can be used directly and is called by
the conTest function if type = "summary".

Usage

```
## S3 method for class 'restriktor'
conTest_summary(object, test = "F", ...)
```

Arguments

object	an object of class restriktor.
test	test statistic; for information about the null-distribution see details.

> • for object of class lm; if "F" (default), the classical F-statistic is computed.
> If "Wald", the classical Wald-statistic is computed. If "score", the classical
> score test statistic is computed.

- for object of class rlm; if "F" (default), a robust likelihood ratio type test statistic (Silvapulle, 1992a) is computed. If "Wald", a robust Wald test statistic (Silvapulle, 1992b) is computed. If "score", a score test statistic (Silvapulle, 1996) is computed.

...   the same arguments as passed to the [iht](#) function, except for type, of course.

Value

An object of class conTest, for which a print is available. More specifically, it is a list with the following items:

CON	a list with useful information about the constraints.
Amat	constraints matrix.
bvec	vector of right-hand side elements.
meq	number of equality constraints.

con_weights_boot	*function for computing the chi-bar-square weights based on Monte Carlo simulation.*

Description

The null-distribution of the test statistics under inequality constraints takes the form of mixtures of F-distributions. This function computes these mixing weights (a.k.a chi-bar-square weights and level probabilities). It can be used directly and is called by the conTest function.

Usage

```
con_weights_boot(VCOV, Amat, meq,
                 R = 99999L, parallel = c("no", "multicore", "snow"),
                 ncpus = 1L, cl = NULL, seed = NULL, verbose = FALSE, ...)
```

Arguments

VCOV	variance-covariance matrix of the data for which the weights are to be calculated.
Amat	constraints matrix R (or a vector in case of one constraint) and defines the left-hand side of the constraint $R\theta \geq rhs$, where each row represents one constraint. The number of columns needs to correspond to the number of parameters estimated (θ). The rows should be linear independent, otherwise the function gives an error. For more information about constructing the matrix R and rhs see [restriktor](#).
meq	integer (default = 0) treating the number of constraints rows as equality constraints instead of inequality constraints. For example, if meq = 2, this means that the first two rows of the constraints matrix R are treated as equality constraints.
R	integer; number of bootstrap draws for mix.bootstrap. The default value is set to 99999.
parallel	the type of parallel operation to be used (if any). If missing, the default is set "no".

ncpus	integer: number of processes to be used in parallel operation: typically one would chose this to the number of available CPUs.
cl	an optional parallel or snow cluster for use if parallel = "snow". If not supplied, a cluster on the local machine is created for the duration of the conTest call.
seed	seed value.
verbose	logical; if TRUE, information is shown at each bootstrap draw.
...	no additional arguments for now.

Value

The function returns a vector with the mixing weights

Author(s)

Leonard Vanbrabant and Yves Rosseel

    evSyn   *GORIC(A) Evidence synthesis*

Description

GORIC(A) evidence synthesis aggregates the evidence for theory-based hypotheses from multiple studies that may use diverse designs to investigate the same central theory.

Usage

```
evSyn(object, ...)

## S3 method for class 'list'
evSyn_est(object, ..., VCOV = list(), hypotheses = list(),
      type = c("equal", "added", "average"),
      comparison = c("unconstrained", "complement", "none"),
      hypo_names = c())
```

```
## S3 method for class 'list'
evSyn_LL(object, ..., PT = list(), type = c("equal", "added", "average"),
        hypo_names = c())

## S3 method for class 'list'
evSyn_ICvalues(object, ..., hypo_names = c())

## S3 method for class 'list'
evSyn_ICweights(object, ..., priorWeights = NULL, hypo_names = c())

## S3 method for class 'evSyn'
print(x, digits = max(3, getOption("digits") - 4), ...)

## S3 method for class 'evSyn'
summary(object, ...)

## S3 method for class 'summary.evSyn'
print(x, digits = max(3, getOption("digits") - 4), ...)

## S3 method for class 'evSyn'
plot(x, ...)
```

Arguments

object	Currently, the following objects can be processed:
	• a list of vectors with (standardized) parameter estimates (the VCOV argument is required);
	• a list of vectors with log-likelihood values (the PT argument is required);
	• a list of vectors with GORIC(A) weights;
	• a list of vectors with GORIC(A) values;
VCOV	a list of covariance matrices of the (standardized) parameter estimates of interest.
PT	a list of vectors with penalty values.
x	an object of class evSyn
type	type of evidence-synthesis approach: Equal-evidence approach (type = "equal"), Added-evidence approach (type = "added"), or Average-evidence approach (type = "average"). See details for more information.
hypotheses	When applying the same set of hypotheses to each study, the syntax structure should be as follows: "hypotheses = list(H1, H2, . . .)". However, if a different set of hypotheses is applied to each study, the syntax structure should be as follows: hypotheses = list(set1 = list(H11, H12), set2 = list(H21, H22)). See goric how to specify the hypotheses syntax or see the example section below.
comparison	if "unconstrained" (default) the unconstrained model is included in the set of models. If "complement" then the restricted object is compared against its complement. Note that the complement can only be computed for one model/hypothesis at a time (for now). If "none" the model is only compared against the models provided by the user.

priorWeights	vector that represents the prior belief for this model. By default, equal prior weights are used (i.e., 1/(#hypotheses)). Notably, in case the prior weights do not sum to 1, it will be rescaled such that it does; which implies that relative importance can be used and not per se weights.
hypo_names	character vector for labelling the hypotheses. By default the names are set to H1, H2, . . .
digits	the number of significant digits to use when printing.
...	This depends on the class of the object.

Details

In the **added-evidence** approach, evidence from each study or dataset is cumulatively aggregated. This means that for every new study, the log-likelihood and the penalty term are added to the cumulative totals. The strength of the aggregated evidence in this approach depends on the nature of the evidence itself. Simply having more studies doesn't necessarily mean stronger evidence if those studies provide weak or contradictory evidence.
Opt for this approach when you anticipate each new piece of evidence to provide an incremental contribution to the overall evidence, without the need to normalize or average across datasets. It's especially suitable when you believe that the aggregated evidence from multiple studies is stronger than if the data were combined into a single study.

The **equal-evidence** approach aggregates the cumulative evidence in the same manner as the added-evidence approach. However, when calculating the GORICA, the cumulative evidence is divided by the number of studies. This ensures that the contribution from each study or dataset remains equal, regardless of the total count. Conceptually, aggregating evidence from multiple studies in this approach can be likened to obtaining evidence from a single larger study, similar to how a meta-analysis treats combined evidence.
Choose this method when you want each study to contribute equally to the overall evidence, irrespective of the size or scope of each individual dataset. It's ideal for situations where you view the combined evidence from multiple studies as equivalent to that from a single, larger study.

The **average-evidence** method can be conceptualized as a form of multiverse analysis. When faced with a single dataset, there are often numerous analytical choices available, such as handling missing data, selecting variables, or choosing statistical methods. Each choice can lead to a different analysis or model, creating a "multiverse" of possible outcomes.
For each of these analyses, an "evidence" score can be calculated, indicating how well the model fits the data. Some models might offer a superior fit, while others might not align as closely with the data. The average-evidence method aggregates these scores, providing an average measure of fit across all considered models. This approach offers an overarching perspective on the general trend across all analyses. If the average evidence suggests a good fit, it indicates that the majority of the chosen analyses align well with the data. This method is invaluable for assessing the robustness of results, ensuring that findings are not merely artifacts of a specific analytical choice but are consistent across various model specifications on the same dataset.
Opt for the average-evidence approach when you wish to gauge the central tendency of evidence across multiple analytical choices. It's especially beneficial when aiming to determine the robustness of results across various model specifications applied to the same dataset.

Value

An object of class evSyn for which a print, summary and plot function is available. The output comprises, among other things, the cumulative and final evidence for the theory-based hypotheses.

evS_Gv <- evSyn(goric.values)
evS_Gv
```

Exam	*Relation between exam scores and study hours, anxiety scores and average point scores.*

Description

The data provide information about students' exam scores, average point score, the amount of study hours and anxiety scores.

Usage

```
data(Exam)
```

Format

A data frame of 20 observations of 4 variables.

Scores exam scores

Hours study hours

Anxiety anxiety scores

APS average point score

References

The original source of these data is http://staff.bath.ac.uk/pssiw/stats2/examrevision.sav.

Examples

```
head(Exam)
```

FacialBurns	*Dataset for illustrating the conTest_conLavaan function.*

Description

A dataset from the Dutch burn center (http://www.adbc.nl). The data were used to examine psychosocial functioning in patients with facial burn wounds. Psychosocial functioning was measured by Anxiety and depression symptoms (HADS), and self-esteem (Rosenberg's self-esteem scale).

Usage

```
data(FacialBurns)
```

Format

A data frame of 77 observations of 6 variables.

Selfesteem Rosenberg's self-esteem scale

HADS Anxiety and depression scale

Age Age measured in years, control variable

TBSA Total Burned Surface Area

RUM Rumination, control variable

Sex Gender, grouping variable

Examples

```
head(FacialBurns)
```

---

goric	*Generalized Order-Restricted Information Criterion (Approximation) Weights*

Description

The goric function computes GORIC(A) weights, which are comparable to the Akaike weights.

Usage

```
goric(object, ...)

## Default S3 method:

## S3 method for class 'con_goric'
coef(object, ...)
```

Arguments

object
: an object containing the outcome of an unconstrained statistical analysis. Currently, the following objects can be processed:
  - a fitted object of class restriktor.
  - a fitted unconstrained object of class lm, rlm or glm.
  - a numeric vector containing the unconstrained estimates resulting from any statistical analysis.
  - a fitted object of class lavaan. See examples on how to specify the hypotheses.
  - a fitted object of class CTmeta.
  - a fitted object of class rma.

x
: an object of class con_goric.

...
: this depends on the class of the object. If object is of class restriktor, further objects of class restriktor can be passed. Note that, the objects have to be of the same class. If object is of class lavaan, the standardized or unstandardized vcov can be used, using setting standardized = TRUE. See details for more information.

hypotheses   a named list; Please note that the hypotheses argument in the given context
                    serves the same purpose as the constraints argument utilized in the restriktor
                    function. The distinction between them is solely semantic.

                    There are two ways to constrain parameters. First, the hypothesis syntax consists
                    of one or more text-based descriptions, where the syntax can be specified as a
                    literal string enclosed by single quotes. Only the names of coef(model) or
                    names(vector) can be used as names. See details for more information. Note
                    that objects of class "mlm" do not (yet) support this method.

                    Second, the hypothesis syntax consists of a matrix R (or a vector in case of
                    one constraint) and defines the left-hand side of the constraint $R\theta \geq rhs$, where
                    each row represents one constraint. The number of columns needs to correspond
                    to the number of parameters estimated (θ) by model. The rows should be linear
                    independent, otherwise the function gives an error. For more information about
                    constructing the matrix R and rhs see details.

comparison   if "unconstrained" (default) the unconstrained model is included in the set of
                    models. If "complement" then the restricted object is compared against its com-
                    plement. Note that the complement can only be computed for one model/hypothesis
                    at a time (for now). If "none" the model is only compared against the models
                    provided by the user.

VCOV   variance-coviance matrix. Only needed if object is of class numeric and type =
                    "gorica" or type = "goricac".

sample.nobs   the number of observations if type = "goricac". Note that, if type = "goricc",
                    the number of observations are inherited from the fitted object.

type   if "goric", the generalized order-restricted information criterion value is com-
                    puted. If "gorica" the log-likihood is computed using the multivariate normal
                    distribution function.

missing   the default setting for objects of class "lm" is listwise: all cases with miss-
                    ing values are removed from the data before the analysis. This is only valid
                    if the data are missing completely at random (MCAR). Another option is to
                    use "two.stage". In this approach, missing data are imputed using an EM al-
                    gorithm. However, we cannot use the complete data as input for futher analy-
                    ses, because the resulting complete data variance-covariance matrix will not be
                    correct. Therefore, we compute the correct aymptotic covariance (Savalei and
                    Bentler, 2009) and use it as input for the goric.numeric function to compute
                    a GORICA(C) value. Note that, the parameter estimates are also recomputed
                    using the complete data.

auxiliary   Vector. The inclusion of auxiliary variables can improve the imputation model.
                    These auxiliary variables are not part of the target model.

emControl   a list of control arguments for the emnorm function from the **norm** package.

standardized   if TRUE, standardized parameter estimates are used.

threshold   integer, The threshold determines the sensitivity in identifying hypotheses with
                    similar log-likilihood values. A smaller threshold will identify only the most
                    similar hypotheses, while a larger threshold will include more hypotheses with a
                    broader range of similarity. Be cautious with equal or nearly equal log-likelihood
                    values as they might indicate support for the boundary of hypotheses or overlap
                    between hypotheses. More details can be found in the Vignette.

auto.bound	not used yet.
digits	the number of significant digits to use when printing.
debug	if TRUE, debugging information is printed out.
brief	if TRUE, a short overview is printed.

Details

The GORIC(A) values themselves are not interpretable and the interest lie in their differences. The GORIC(A) weights reflect the support of each hypothesis in the set. To compare two hypotheses (and not one to the whole set), one can examine the ratio of the two corresponding GORIC(A) weights. To avoid selecting a weakly supported hypothesis as the best one, the unconstrained hypothesis is usually included as safeguard.

In case of one order-constrained hypothesis, say H1, the complement Hc can be computed as competing hypothesis. The complement is defined as Hc = not H1.

If the object(s) is of class restriktor the hypotheses (constraints) are inherited. Otherwise, the hypothesis syntax can be parsed via the hypotheses argument. If the object is an unconstrained model of class `lm`, `rlm` or `glm`, then the hypotheses can be specified in two ways, see `restriktor`. Note that if the hypotheses are written in matrix notation, then the hypotheses for each model/hypothesis is put in a named list with specific names constraints, rhs, and neq. For example with three parameters x1, x2, x3, and x1 > 0: list(model1 = list(constraints = rbind(c(1, 0, 0)), rhs = 0, neq = 0))). The rhs and neq are not required if they are equal to 0. If type = "gorica", then the object might be a (named) numeric vector. The hypotheses can again be specified in two ways, see `restriktor`. For examples, see below.

To determine the penalty term values, the chi-bar-square weights (a.k.a. level probabilities) must be computed. If `"mix.weights = "pmvnorm" "` (default), the chi-bar-square weights are computed based on the multivariate normal distribution function with additional Monte Carlo steps. If `"mix.weights = "boot" "`, the chi-bar-square weights are computed using parametric bootstrapping (see `restriktor`).

The "two.stage" approach for missing data uses the EM algorithm from the `norm` package. The response variables are assumed to be jointly normal. In practice, missing-data procedures designed for variables that are normal are sometimes applied to variables that are not. Binary and ordinal variables are sometimes imputed under a normal model, and the imputed values may be classified or rounded. This is also how restriktor handles (ordered) factors for now.

A better strategy (not implemented yet) would be to convert (ordered) factors into a pair of dummy variables. If the (ordered) factors have missing values, the dummy variables could be included as columns of Y and imputed, but then you have to decide how to convert the continuously distributed imputed values for these dummy codes back into categories.

Note on not full row-rank

If the restriction matrix is not of full row-rank, this means one of the following:

- There is at least one redundant restriction specified in the hypothesis. Then, either
  - [a] Leave the redundant one out
  - [b] Use another (more time-consuming) way of obtaining the level probabilities for the penalty term (goric function does this by default): Bootstrapping, as discussed above.

- There is at least one range restriction (e.g., -2 < group1 < 2). Such a restriction can be evalu-
  ated but there is a sensitivity (of a scaling factor in the covariance matrix, like with a prior in
  a Bayes factor) which currently cannot be checked for.
- There is at least one conflicting restriction (e.g., 2 < group1 < -2).

Such a restriction can evidently never hold and is thus impossible to evaluate. To prevent this type
of error delete the one that is incorrect.

Value

The function returns a dataframe with the log-likelihood, penalty term, GORIC(A) values and the
GORIC(A) weights. Furthermore, a dataframe is returned with the relative GORIC(A) weights.

```

Hurricanes   *The Hurricanes Dataset*

Description

The data provide information on the effect of El Nino (Cold, Neutral, Warm) on the number of hurricanes from 1950 to 1995.

Usage

```
data(Hurricanes)
```

Format

A data frame of 46 observations of 3 variables.

Year

Hurricanes Number of Hurricanes

ElNino 1=Cold, 2=Neutral, 3=Warm

References

The original source of these data is the National Hurricane Center in Australia. The dataset was extracted from the table on page 5 in Silvapulle and Sen (2005).

Examples

```
head(Hurricanes)
```

---

iht   *function for informative hypothesis testing (iht)*

Description

`iht` tests linear equality and/or inequality restricted hypotheses for linear models.

Usage

```
iht(...)

conTest(object, constraints = NULL, type = "summary", test = "F",
        rhs = NULL, neq = 0, ...)

conTestD(model = NULL, data = NULL, constraints = NULL,
         type = c("A","B"), R = 1000L, bootstrap.type = "bollen.stine",
         return.test = TRUE, neq.alt = 0,
         double.bootstrap = "standard", double.bootstrap.R = 249,
         double.bootstrap.alpha = 0.05,
         parallel = c("no", "multicore", "snow"),
         ncpus = 1L, cl = NULL, verbose = FALSE, ...)
```

Arguments

object	an object of class `lm` or `rlm`. In this case, the constraint syntax needs to be specified
	OR
	an object of class `restriktor`. The constraints are inherited from the fitted restriktor object and do not to be specified again.
model	lavaan model syntax specifying the model. See [model.syntax](#) for more information.
constraints	there are two ways to constrain parameters. First, the constraint syntax consists of one or more text-based descriptions, where the syntax can be specified as a literal string enclosed by single quotes. Only the names of `coef(model)` can be used as names. See details [restriktor](#) for more information.
	Second, the constraint syntax consists of a matrix R (or a vector in case of one constraint) and defines the left-hand side of the constraint $R\theta \geq rhs$, where each row represents one constraint. The number of columns needs to correspond to

	the number of parameters estimated (θ) by model. The rows should be linear independent, otherwise the function gives an error. For more information about constructing the matrix R and rhs see the details in the [restriktor](#) function.
data	the data frame containing the observed variables being used to fit the lavaan model.
type	hypothesis test type "A", "B", "C", "global", or "summary" (default). See details for more information.
test	test statistic; for information about the null-distribution see details.

- for object of class lm; if "F" (default), the F-bar statistic (Silvapulle, 1996) is computed. If "LRT", a likelihood ratio test statistic (Silvapulle and Sen, 2005, chp 3.) is computed. If "score", a global score test statistic (Silvapulle and Silvapulle, 1995) is computed. Note that, in case of equality constraints only, the usual unconstrained F-, Wald-, LR- and score-test statistic is computed.
- for object of class rlm; if "F" (default), a robust likelihood ratio type test statistic (Silvapulle, 1992a) is computed. If "Wald", a robust Wald test statistic (Silvapulle, 1992b) is computed. If "score", a global score test statistic (Silvapulle, and Silvapulle, 1995) is computed. Note that, in case of equality constraints only, unconstrained robust F-, Wald-, score-test statistics are computed.
- for object of class glm; if "F" (default), the F-bar statistic (Silvapulle, 1996) is computed. If "LRT", a likelihood ratio test statistic (Silvapulle and Sen, 2005, chp 4.) is computed. If "score", a global score test statistic (Silvapulle and Silvapulle, 1995) is computed. Note that, in case of equality constraints only, the usual unconstrained F-, Wald-, LR- and score-test statistic is computed.

rhs	vector on the right-hand side of the constraints; $R\theta \geq rhs$. The length of this vector equals the number of rows of the constraints matrix R and consists of zeros by default. Note: only used if constraints input is a matrix or vector.
neq	integer (default = 0) treating the number of constraints rows as equality constraints instead of inequality constraints. For example, if neq = 2, this means that the first two rows of the constraints matrix R are treated as equality constraints. Note: only used if constraints input is a matrix or vector.
neq.alt	integer: number of equality constraints that are maintained under the alternative hypothesis (for hypothesis test type "B").
R	Integer; number of bootstrap draws. The default value is set to 1000.
bootstrap.type	If "parametric", the parametric bootstrap is used. If "bollen.stine", the semi-nonparametric Bollen-Stine bootstrap is used. The default is set to "bollen.stine".
return.test	Logical; if TRUE, the function returns bootstrapped test-values.
double.bootstrap	
	If "standard" (default) the genuine double bootstrap is used to compute an additional set of plug-in p-values for each bootstrap sample. If "no", no double bootstrap is used. If "FDB", the fast double bootstrap is used to compute second level LRT-values for each bootstrap sample. Note that the "FDB" is experimental and should not be used by inexperienced users.

double.bootstrap.R

        Integer; number of double bootstrap draws. The default value is set to 249.

double.bootstrap.alpha

        The significance level to compute the adjusted alpha based on the plugin p-values. Only used if double.bootstrap = "standard". The default value is set to 0.05.

parallel   The type of parallel operation to be used (if any). If missing, the default is set "no".

ncpus   Integer: number of processes to be used in parallel operation: typically one would chose this to the number of available CPUs.

cl   An optional parallel or snow cluster for use if parallel = "snow". If not supplied, a cluster on the local machine is created for the duration of the InformativeTesting call.

verbose   Logical; if TRUE, information is shown at each bootstrap draw.

...   futher options for the iht and/or restriktor function. See details for more information.

Details

The following hypothesis tests are available:

- Type A: Test H0: all constraints with equalities ("=") active against HA: at least one inequality restriction (">") strictly true.

- Type B: Test H0: all constraints with inequalities (">") (including some equalities ("=")) active against HA: at least one restriction false (some equality constraints may be maintained).

- Type C: Test H0: at least one restriction false ("<") against HA: all constraints strikty true (">"). This test is based on the intersection-union principle (Silvapulle and Sen, 2005, chp 5.3). Note that, this test only makes sense in case of no equality constraints.

- Type global: equal to Type A but H0 contains additional equality constraints. This test is analogue to the global F-test in lm, where all coefficients but the intercept equal 0.

The null-distribution of hypothesis test Type C is based on a t-distribution (one-sided). Its power can be poor in case of many inequalty constraints. Its main role is to prevent wrong conclusions from significant results from hypothesis test Type A.

The exact finite sample distributions of the non-robust F-, score- and LR-test statistics based on restricted OLS estimates and normally distributed errors, are a mixture of F-distributions under the null hypothesis (Wolak, 1987). For the robust tests, we found that the results based on these mixtures of F-distributions approximate the tail probabilities better than their asymptotic distributions.

Note that, in case of equality constraints only, the null-distribution of the (non-)robust F-test statistics are based on an F-distribution. The (non-)robust Wald- and (non-)robust score-test statistics are based on chi-square distributions.

If object is of class lm or rlm, the conTest function internally calls the restriktor function. Arguments for the restriktor function can be passed on via the .... Additional arguments for the conTest function can also passed on via the .... See for example conTestF for all available arguments.

Value

An object of class conTest or conTestLavaan for which a print is available.

iht-methods   *Methods for iht*

Description

Print function for objects of class conTest.

Usage

```
## S3 method for class 'conTest'
print(x, digits = max(3, getOption("digits") - 2), ...)
```

Arguments

`x`	an object of class `conTest`.
`digits`	the number of significant digits to use when printing.
`...`	no additional arguments for now.

Value

No return value, just the result of the print function

Examples

```
# unrestricted linear model for ages (in months) at which an
# infant starts to walk alone.

# prepare data
DATA <- subset(ZelazoKolb1972, Group != "Control")

# fit unrestricted linear model
fit.lm <- lm(Age ~ -1 + Group, data = DATA)

# restricted linear model with restrictions that the walking
# exercises would not have a negative effect of increasing the
# mean age at which a child starts to walk.
fit.con <- restriktor(fit.lm, constraints = "GroupActive < GroupPassive < GroupNo")

iht(fit.con)
```

---

myGORICs	*An example of IC values*

Description

An example of IC: A matrix with information criteria (AIC, ORIC, GORIC, or GORICA) values of size 4 x 3 (in general: S x 'NrHypos+1', where 'NrHypos+1' stands for the number of theory-based hypotheses plus a safeguard hypothesis (the complement or unconstrained)).

Usage

```
data(myGORICs)
```

Format

An object of class `matrix` (inherits from `array`) with 4 rows and 3 columns.

Examples

```
data(myGORICs)
```

---

myLLs   *An example of log likelihood (LL) values*

Description

An example of LL: A matrix with log likelihood values of size 4 x 3 (in general: S x 'NrHypos+1', where 'NrHypos+1' stands for the number of theory-based hypotheses plus a safeguard hypothesis (the complement or unconstrained)).

Usage

```
data(myLLs)
```

Format

An object of class matrix (inherits from array) with 4 rows and 3 columns.

Examples

```
data(myLLs)
```

---

myPTs   *An example of penalty (PT) values*

Description

An example of PT: A matrix with penalty values of size 4 x 3 (in general: S x 'NrHypos+1', where 'NrHypos+1' stands for the number of theory-based hypotheses plus a safeguard hypothesis (the complement or unconstrained)).

Usage

```
data(myPTs)
```

Format

An object of class matrix (inherits from array) with 4 rows and 3 columns.

Examples

```
data(myPTs)
```

---

restriktor   *Estimating linear regression models with (in)equality restrictions*

Description

Function `restriktor` estimates the parameters of an univariate and a multivariate linear model (`lm`), a robust estimation of the linear model (`rlm`) and a generalized linear model (`glm`) subject to linear equality and linear inequality restrictions. It is a convenience function. The real work horses are the `conLM`, `conMLM`, `conRLM` and the `conGLM` functions.

Usage

```
restriktor(object, constraints = NULL, ...)

## S3 method for class 'lm'
conLM(object, constraints = NULL, se = "standard",
      B = 999, rhs = NULL, neq = 0L, mix.weights = "pmvnorm",
      mix.bootstrap = 99999L, parallel = "no", ncpus = 1L,
      cl = NULL, seed = NULL, control = list(),
      verbose = FALSE, debug = FALSE, ...)

## S3 method for class 'rlm'
conRLM(object, constraints = NULL, se = "standard",
       B = 999, rhs = NULL, neq = 0L, mix.weights = "pmvnorm",
       mix.bootstrap = 99999L, parallel = "no", ncpus = 1L,
       cl = NULL, seed = NULL, control = list(),
       verbose = FALSE, debug = FALSE, ...)

## S3 method for class 'glm'
conGLM(object, constraints = NULL, se = "standard",
       B = 999, rhs = NULL, neq = 0L, mix.weights = "pmvnorm",
       mix.bootstrap = 99999L, parallel = "no", ncpus = 1L,
       cl = NULL, seed = NULL, control = list(),
       verbose = FALSE, debug = FALSE, ...)

## S3 method for class 'mlm'
conMLM(object, constraints = NULL, se = "none",
       B = 999, rhs = NULL, neq = 0L, mix.weights = "pmvnorm",
       mix.bootstrap = 99999L, parallel = "no", ncpus = 1L,
       cl = NULL, seed = NULL, control = list(),
       verbose = FALSE, debug = FALSE, ...)
```

Arguments

object   a fitted linear model object of class "lm", "mlm", "rlm" or "glm". For class "rlm"
                  only the loss function `bisquare` is supported for now, otherwise the function
                  gives an error.

constraints   there are two ways to constrain parameters. First, the constraint syntax consists
                 of one or more text-based descriptions, where the syntax can be specified as a
                 literal string enclosed by single quotes. Only the names of coef(model) can
                 be used as names. See details for more information. Note that objects of class
                 "mlm" do not (yet) support this method.

                 Second, the constraint syntax consists of a matrix R (or a vector in case of one
                 constraint) and defines the left-hand side of the constraint $R\theta \geq rhs$, where each
                 row represents one constraint. The number of columns needs to correspond to
                 the number of parameters estimated (θ) by model. The rows should be linear
                 independent, otherwise the function gives an error. For more information about
                 constructing the matrix R and rhs see details.

se   if "standard" (default), conventional standard errors are computed based on in-
                 verting the observed augmented information matrix. If "const", homoskedas-
                 tic standard errors are computed. If "HC0" or just "HC", heteroskedastic ro-
                 bust standard errors are computed (a.k.a Huber White). The options "HC1",
                 "HC2", "HC3", "HC4", "HC4m", and "HC5" are refinements of "HC0". For more
                 details about heteroskedastic robust standard errors see the **sandwich** pack-
                 age. If "boot.standard", bootstrapped standard errors are computed using
                 standard bootstrapping. If "boot.model.based" or "boot.residual", boot-
                 strapped standard errors are computed using model-based bootstrapping. If
                 "none", no standard errors are computed. Note that for objects of class "mlm"
                 no standard errors are available (yet).

B   integer; number of bootstrap draws for se. The default value is set to 999.
                 Parallel support is available.

rhs   vector on the right-hand side of the constraints; $R\theta \geq rhs$. The length of this
                 vector equals the number of rows of the constraints matrix R and consists of
                 zeros by default. Note: only used if constraints input is a matrix or vector.

neq   integer (default = 0) treating the number of constraints rows as equality con-
                 straints instead of inequality constraints. For example, if neq = 2, this means
                 that the first two rows of the constraints matrix R are treated as equality con-
                 straints. Note: only used if constraints input is a matrix or vector.

mix.weights   if "pmvnorm" (default), the chi-bar-square weights are computed based on the
                 multivariate normal distribution function with additional Monte Carlo steps. If
                 "boot", the chi-bar-square weights are computed using parametric bootstrap-
                 ping. If "none", no chi-bar-square weights are computed. The weights are nec-
                 essary in the restriktor.summary function for computing the GORIC. More-
                 over, the weights are re-used in the [iht](#) function for computing the p-value for
                 the test-statistic, unless the p-value is computed directly via bootstrapping.

mix.bootstrap   integer; number of bootstrap draws for mix.weights = "boot". The default
                 value is set to 99999. Parallel support is available.

parallel   the type of parallel operation to be used (if any). If missing, the default is set
                 "no".

ncpus   integer: number of processes to be used in parallel operation: typically one
                 would chose this to the number of available CPUs.

cl   an optional parallel or snow cluster for use if parallel = "snow". If not supplied,
                 a cluster on the local machine is created for the duration of the restriktor call.

seed	seed value.
control	a list of control arguments:

- `absval` tolerance criterion for convergence (default = sqrt(.Machine$double.eps)).
- `maxit` the maximum number of iterations for the optimizer (default = 10000).
- `tol` numerical tolerance value. Estimates smaller than `tol` are set to 0.

verbose	logical; if TRUE, information is shown at each bootstrap draw.
debug	if TRUE, debugging information about the constraints is printed out.
...	no additional arguments for now.

Details

The constraint syntax can be specified in two ways. First as a literal string enclosed by single quotes as shown below:

```
myConstraints <- '
    # 1. inequality constraints
      x1 > 0
      x1 < x2
    # or
      0 < x1 < x2

    ! 2. equality constraints
      x3 == x4; x4 == x5
    # or
      x3 = x4; x4 = x5
    # or
      x3 = x4 = x5'
```

The variable names x1 to x5 refer to the corresponding regression coefficient. Thus, constraints are impose on regression coefficients and not on the data.

Second, the above constraints syntax can also be written in matrix/vector notation as:

(The first column refers to the intercept, the remaining five columns refer to the regression coefficients x1 to x5.)

```
myConstraints <-
    rbind(c(0, 0, 0,-1, 1, 0), #equality constraint x3 = x4
          c(0, 0, 0, 0,-1, 1), #equality constraint x4 = x5
          c(0, 1, 0, 0, 0, 0), #inequality constraint x1 > rhs
          c(0,-1, 1, 0, 0, 0)) #inequality constraint x1 < x2

# the length of rhs is equal to the number of myConstraints rows.
myRhs <- c(0,0,0,0)

# the first two rows should be considered as equality constraints
myNeq <- 2
```

Blank lines and comments can be used in between the constraints, and constraints can be split over multiple lines. Both the hashtag (#) and the exclamation (!) characters can be used to start a comment. Multiple constraints can be placed on a single line if they are separated by a semicolon (;), a comma (,) or the "&" sign.

In addition compound constraints can be stated via one or more longer equality or inequality sentences e.g., 'x1 > x2 > x3; x3 < 4 < x4' or 'x1 == x2 == x3 & x4 = 1'. Alternatively, the constrains can be specifies as '(x1, x2) > (x3, x4)' which is equivalent to 'x1 > x3; x1 > x4; x2 > x3; x2 > x4'.

There can be three types of text-based descriptions in the constraints syntax:

1. Equality constraints: The "==" or "=" operator can be used to define equality constraints (e.g., x1 = 1 or x1 = x2).

2. Inequality constraints: The "<" or ">" operator can be used to define inequality constraints (e.g., x1 > 1 or x1 < x2).

3. Newly defined parameters: The ":=" operator can be used to define new parameters, which take on values that are an arbitrary function of the original model parameters. The function must be specified in terms of the parameter names in coef(model) (e.g., new := x1 + 2*x2). By default, the standard errors for these defined parameters are computed by using the so-called Delta method.

Variable names of interaction effects in objects of class lm, rlm and glm contain a semi-colon (:) between the variables. To impose constraints on parameters of interaction effects, the semi-colon must be replaced by a dot (.) (e.g., x3:x4 becomes x3.x4). In addition, the intercept variable names is shown as "(Intercept)". To impose restrictions on the intercept both parentheses must be replaced by a dot ".Intercept." (e.g.,.Intercept. > 10). Note: in most practical situations we do not impose restrictions on the intercept because we do not have prior knowledge about the intercept. Moreover, the sign of the intercept can be changed arbitrarily by shifting the response variable y.

Each element can be modified using arithmetic operators. For example, if x2 is expected to be twice as large as x1, then "2*x2 = x1".

If constraints = NULL, the unrestricted model is fitted.

Note on not full row-rank

If the restriction matrix is not of full row-rank, this means one of the following:

- There is at least one redundant restriction. Then, either
    - [a] Leave the redundant one out
    - [b] Use another (more time-consuming) way of obtaining the level probabilities for the penalty term (goric function does this by default): Bootstrapping, as discussed above.
- There is at least one range restriction (e.g., -2 < group1 < 2). Such a restriction can be evaluated but there is a sensitivity (of a scaling factor in the covariance matrix, like with a prior in a Bayes factor) which currently cannot be checked for.
- There is at least one conflicting restriction (e.g., 2 < group1 < -2).

Such a restriction can evidently never hold and is thus impossible to evaluate. To prevent this type of error delete the one that is incorrect.

Value

An object of class restriktor, for which a print and a summary method are available. More specifi-
cally, it is a list with the following items:

CON	a list with useful information about the restrictions.
call	the matched call.
timing	how much time several tasks take.
parTable	a parameter table with information about the observed variables in the model and the imposed restrictions.
b.unrestr	unrestricted regression coefficients.
b.restr	restricted regression coefficients.
residuals	restricted residuals.
wresid	a working residual, weighted for "inv.var" weights only (rlm only)
fitted	restricted fitted mean values.
weights	(only for weighted fits) the specified weights.
wgt	the weights used in the IWLS process (rlm only).
scale	the robust scale estimate used (rlm only).
stddev	a scale estimate used for the standard errors.
R2.org	unrestricted R-squared.
R2.reduced	restricted R-squared.
df.residual	the residual degrees of freedom
s2.unrestr	mean squared error of unrestricted model.
s2.restr	mean squared error of restricted model.
loglik	restricted log-likelihood.
Sigma	variance-covariance matrix of unrestricted model.
constraints	matrix with restrictions.
rhs	vector of right-hand side elements.
neq	number of equality restrictions.
wt.bar	chi-bar-square mixing weights or a.k.a. level probabilities.
iact	active restrictions.
converged	did the IWLS converge (rlm only)?
iter	number of iteration needed for convergence (rlm only).
bootout	object of class boot. Only available if bootstrapped standard errors are re-quested, else bootout = NULL.
control	list with control options.
model.org	original model.
se	as input. This information is needed in the summary function.
information	observed information matrix with the inverted information matrix and the aug-mented information matrix as attributes.

restriktor-methods   *Methods for restriktor*

Description

restricted estimation and confidence intervals for (robust) linear (in)equality restricted hypotheses.

Usage

```
## S3 method for class 'restriktor'
print(x, digits = max(3, getOption("digits") - 2), ...)

## S3 method for class 'restriktor'
summary(object, bootCIs = TRUE,
        bty = "perc", level = 0.95, goric = "goric", ...)

## S3 method for class 'summary.restriktor'
print(x, digits = max(3, getOption("digits") - 2),
              signif.stars = getOption("show.signif.stars"), ...)

## S3 method for class 'restriktor'
coef(object, ...)

## S3 method for class 'restriktor'
model.matrix(object, ...)

## S3 method for class 'restriktor'
logLik(object, ...)
```

Arguments

`object`	an object of class `restriktor`.
`x`	an object of class `restriktor`.
`bootCIs`	if TRUE (default), nonparametric bootstrap confidence intervals are generated. Only available if `object` contains bootout object.
`bty`	a character string representing the type of interval required. The value should be any of the values `"norm"`, `"basic"`,`"perc"`,`"bca"`. The value `"stud"` is not supported. For more details see [`boot.ci`](boot.ci).
`level`	the confidence level of the interval (default = 0.95).
`goric`	if `"goric"` (default), the generalized order-restricted information criterion value is computed. If `"gorica"` the log-likihood is computed using the multivariate normal distribution function. If `"goricc"` or `"goricca"`, a small sample version of the `"goric"` or `"gorica"` is computed.
`digits`	the number of significant digits to use when printing.
`signif.stars`	If TRUE, "significance stars are printed for each coefficient.
`...`	no additional arguments for now.

Details

The function `print` returns the restricted coefficients. The output from the `print.summary.conLM` function provides information that is comparable with the output from `print.summary.lm`. Additional information is provided about the unrestricted and restricted R-square and by default the output of the GORIC. If bootstrapped standard errors are requested (e.g., option se = `"boot.model.based"`

in the `restriktor` function and `bootCI = TRUE` in the summary function) standard errors and confidence intervals are provided.

Value

The function `summary` computes and returns a list of summary statistics of the fitted unrestricted and restricted (robust) linear model given in `object`, plus

`se.type`	type of standard error computed, equal to input `se` in the `restriktor` function.
`residuals`	the weighted residuals.
`coefficients`	a p x 4 matrix with columns for the estimated coefficient, its standard error, t-statistic and corresponding p-value. If `bootCIs = TRUE` and the bootout object is available in the object, bootstrapped standard errors and confidence intervals are produced.
`rdf`	residual degrees of freedom.
`R2.org`	unrestricted R-squared.
`R2.reduced`	restricted R-squared.
`goric`	goric value and attributed its penalty term and log-likelihood.

Examples

```
# unrestricted linear model for ages (in months) at which an
# infant starts to walk alone.

# prepare data
DATA <- subset(ZelazoKolb1972, Group != "Control")

# fit unrestricted linear model
fit.lm <- lm(Age ~ -1 + Group, data = DATA)

# restricted linear model with restrictions that the walking
# exercises would not have a negative effect of increasing the
# mean age at which a child starts to walk.
fit.con <- restriktor(fit.lm, constraints = ' GroupActive  < GroupPassive < GroupNo ')

summary(fit.con)
```

ZelazoKolb1972   *"Walking" in the newborn (4 treatment groups)*

Description

The Zelazo, Zelazo and Kolb (1972) dataset consists of ages (in months) at which an infant starts to walk alone from four different treatment groups (Active-exercise, Passive-exercise, 8 week Control, No-exercise).

Usage

```
data(ZelazoKolb1972)
```

Format

A data frame of 23 observations of 4 treatment variables.

Age   Age in months

Group   Active-exercise, Passive-exercise, 8-week Control group, No-exercise
